Dotfiles

These are all my config files. There are two branches; master and gentoo. Master is for my arch machine and gentoo is for my gentoo machine. They're mostly the same, but if you're not a gentoo user then I recommend you pull from the master branch instead.

What I use

I use Dwm, fish shell, neovim and most of suckless' tools. Dwm might be the easiest window manager to configure, you don't need to know any C at all. They're a few videos on YouTube on how to patch it, and once you're done, you never have to tweak it again. There's a `patches` directory with a list of all the patches.

The zsh config I took from Chris the machine.

A lot of my stuff I've forked or borrowed from Luke Smith. You'll find I have his:

- Scripts for a lot of useful stuff

- Fork of st

- Lf settings

- Sxiv settings

- mutt-wizard

You'll notice that my file structure looks different. That's because I'm using GNU stow. Here's a video from Chris the machine explaining how to use it. He's also the main developer for lunarvim.

Installing

Download `stow` and `git`.

Clone into your `$HOME` directory or ~.

git clone https://github.com/cmpi66/dotfiles.git ~

Run `stow` to symlink everything or select any config files you want.

```
stow */ # this gets everything; the '/' ignores the README
stow fish # Only my fish config
```
